11. Integer Linear Programming and Introduction to Approximation

CPSC 535

Kevin A. Wortman

CALIFORNIA STATE UNIVERSITY
FULLERTON

Recall: General LP Problem

general-form linear programming problem
input:

- Boolean for whether f is maximized/minimized
- vector $c \in \mathbb{R}^n$
- vector $b \in \mathbb{R}^m$
- vector $o \in \{\leq, =, \geq\}^m$
- $m \times n$ matrix A of real numbers

output: one of

1. "unbounded";
2. "infeasible"; or
3. "solution" with a vector $x \in \mathbb{R}^n$ maximizing the objective function

Recall: Reduction Algorithm

```
1: function SOLVE-A(input-for-A)
2:     input-for-B = pre-process input-for-A
3:     solution-for-B = solve-B(input-for-B)
4:     solution-for-A = post-process solution-for-B
5:     return solution-for-A
6: end function
```

Algorithms that Reduce to LP

```
1: function SOLVE-A(input-for-A)
2:     program = convert input-for-A to linear program
3:     result = solve-B(input-for-B)
4:     if result is "unbounded" then
5:         return output-for-unbounded-case
6:     else if result is "infeasible" then
7:         return output-for-infeasible-case
8:     else
9:         solution-for-A = convert LP solution
10:        return solution-for-A
11:    end if
12: end function
```

Integer Linear Programming

- **integer** *linear programming:* like general form, but all variables are integers instead of real
- i.e. each $x_i \in \mathbb{Z}$
- *Mixed Integer Programming (MIP):* mixture of real and integer variables
- i.e. a subset $I \subseteq \{x_1, \ldots, x_n\}$ of variables are restricted to integers

MIP problem

mixed-integer programming problem (MIP)

input:

- Boolean for whether f is maximized/minimized
- vector $c \in \mathbb{R}^n$
- vector $b \in \mathbb{R}^m$
- vector $o \in \{\leq, =, \geq\}^m$
- $m \times n$ matrix A of real numbers
- set $I \subset \{1, \ldots, n\}$

output: one of

1. "unbounded";
2. "infeasible"; or
3. "solution" with a vector $x \in \mathbb{R}^n$ maximizing the objective function; if $i \in I$ then $x_i \in \mathbb{Z}$

MIP Applications

- **discrete variables:** can formulate a business-logic whole number concept with
  - variable $x_i, i \in I$
  - example: you can buy 3 or 4 airplanes but not 3.7
- **true/false decision:** can formulate a true/false choice with
  - variable x_i, $i \in I$
  - constraints $0 \leq x_i$ and $x_i \leq 1$
- **choose among k alternatives:** more generally, can formulate a choice from $\{a, \ldots, b\} \subset \mathbb{Z}$ with
  - variable $x_i, i \in I$
  - constraints $a \leq x_i$ and $x_i \leq b$

MIP Hardness

- Recall: hardness of general LP is an open question
- not proven in P, not proven NP-hard
- MIP **is** NP-complete
- specifying integer variables seems to make the problem substantially harder
- worst-case MIP programs are intractible
- **but** MIP solvers use lots of clever heuristics
- so specific MIP formulations are often computationally feasible in practice

Vertex Cover

vertex cover problem
input: an undirected graph $G = (V, E)$
output: a vertex cover C of minimum size

vertex cover: a subset $C \subseteq V$ such that, if $(u, v) \in E$, then $u \in C$ or $v \in C$ (or both)

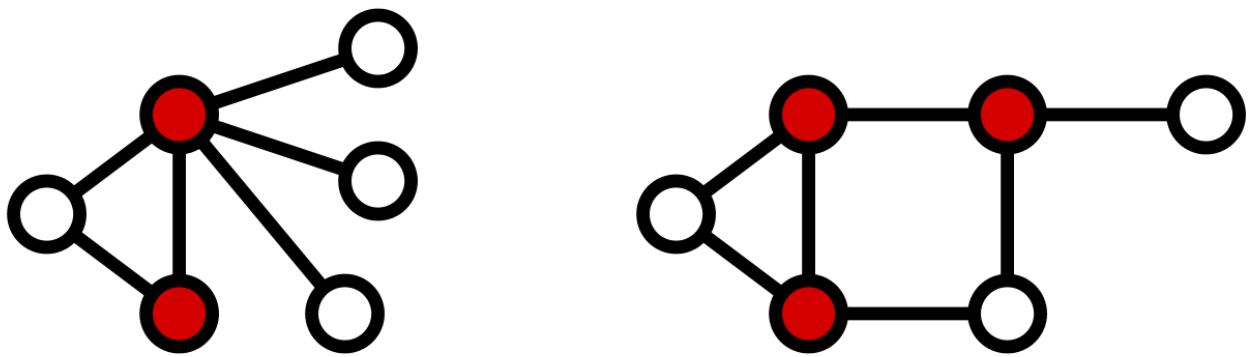

Image credit: https://commons.wikimedia.org/wiki/File:Minimum-vertex-cover.svg

Formulating Vertex Cover

Recall:

- vertex cover is *NP*-complete
- if vertex cover can be formulated as a MIP problem, then MIP is *NP*-hard

"Rules" to represent:

- each vertex is either in C or not
- each edge has at least one end in C
- minimize $|C|$

Formulating Vertex Cover

Variables: for each $v \in V$, create an integer variable x_v such that

$$x_v = 1 \Leftrightarrow v \in C$$

Objective: minimize

$$\sum_{v \in V} x_v$$

Constraints:

$0 \leq x_v \leq 1$	$\forall v \in V$	(0 or 1 indicator)
$x_u + x_v \geq 1$	$\forall (u, v) \in E$	(each edge is covered)

Vertex Cover Outcomes

- **Infeasible:**
  - never happens
  - $\exists$ a solution: setting all $x_v = 1$ satisfies all constraints
- **Unbounded:**
  - never happens
  - objective is bounded: the objective function is to minimize

$$\sum_{v \in V} x_v;$$

since every $x_v \geq 0$, the minimum objective value is zero, which is finite, so the program is never unbounded

- **Solution:** Construct C as

$$C = \{v \mid v \in V \text{ and } x_v = 1\}$$

TSP

traveling salesperson problem (TSP)
input: a complete, weighted, undirected graph $G = (V, E)$
output: a tour T of minimum weight

tour: a sequence of vertices $\langle t_1, \ldots, t_n \rangle$ that visits each vertex exactly once *Hamiltonian cycle*

Define:

$$n \equiv |V|$$

$$w(u, v) \equiv \text{ the weight of the edge from } u \text{ to } v$$

Formulating TSP

"Rules" to represent:

- each vertex is visited exactly once
- minimize total weight

Formulating TSP

Variables: for each $u \in V$ and $v \in V$, create an integer variable $x_{u,v}$ such that

$$x_{u,v} = 1 \Leftrightarrow \text{ the tour steps from } u \text{ to } v$$

Objective: minimize

$$\sum_{u,v \in V} w(u,v) \cdot x_{u,v}$$

Constraints:

$0 \leq x_{u,v} \leq 1$	$\forall u, v \in V$	(0 or 1 indicator)
$\sum_{u \in V} x_{u,v} = 1$	$\forall v \in V$	(each vertex is entered once)
$\sum_{v \in V} x_{u,v} = 1$	$\forall u \in V$	(each vertex is exited once)
$\sum_{u,v \in V} x_{u,v} = n$		(tour has n edges)

TSP Outcomes

- **Infeasible:**
  - never happens
  - $\exists$ a solution: G is complete, so certainly contains at least one tour
- **Unbounded:**
  - never happens
  - objective is bounded: observe that $\sum_{u,v \in V} w(u,v) \cdot x_{u,v}$ is minimized when every $x_{u,v}$ is zero; so the minimum objective value is zero; which is finite.
- **Solution:** Construct $T = \langle t_1, \ldots, t_n \rangle$ as

$$t_i = \begin{cases} \text{an arbitrary } v \in V & i = 1 \\ v \text{ such that } x_{t_{i-1},v} = 1 & i > 1 \end{cases}$$

Formulating Sudoku

Sudoku: input is a $9x9$ grid, some cells are integers $\{1, \ldots, 9\}$, others are blank

			2	6		7		1
6	8			7			9	
1	9				4	5		
8	2		1				4	
		4	6		2	9		
	5				3		2	8
		9	3				7	4
	4			5			3	6
7		3		1	8			

Rules:

1. Objective: fill every blank
2. Each row contains $\{1, \ldots, 9\}$
3. Each column contains $\{1, \ldots, 9\}$
4. Each 3×3 subgrid contains $\{1, \ldots, 9\}$
5. (implies none of these regions has duplicates)

Formulating Sudoku: Variables

Create binary decision variables

$$x_{ijv} = 1 \Leftrightarrow \text{ row } i, \text{ column } j, \text{ is assigned value } v$$

Specify that every x_{ijv} is an integer variable.

Add constraints for the variables to be used properly:

$$0 \leq x_{ijv} \leq 1 \qquad \forall i, j, v \in \{1, \ldots, 9\} \qquad \text{(0 or 1 indicator)}$$
$$\sum_{v=1}^{9} x_{ijv} = 1 \qquad \forall i, j \in \{1, \ldots, 9\} \qquad \text{(each cell has exactly one value)}$$

Rule 1: Pre-Filled Cells

For each pre-filled cell at row i, column j, filled with value v, add one constraint

$$x_{ijv} = 1$$

Rules 2, 3: Each Row, Column is Filled Properly

"Row i is filled in properly" $\Leftrightarrow$ each value v appears exactly once in row i
(and for columns, resp.)

Add constraints:

$$\sum_{j=1}^{9} x_{ijv} = 1 \quad \forall i, v \in \{1, \ldots, 9\} \quad \text{rows are filled properly}$$
$$\sum_{i=1}^{9} x_{ijv} = 1 \quad \forall j, v \in \{1, \ldots, 9\} \quad \text{columns are filled properly}$$

Rule 4: Each Subgrid is Filled Properly

For $r, c \in \{1, 2, 3\}$, let

$G(r, c) = \{(i, j) : i, j \in \{1, \ldots, 9\}$ and (i, j) is a cell of subgrid $r, c\}$.

Add constraints:

$\sum_{(i,j) \in G(r,c)} x_{ijv} = 1 \quad \forall v \in \{1, \ldots 9\}; r, c \in \{1, 2, 3\}$ subgrids

Objective Function

- Those constraints model all the rules of Sudoku!
- Still need an objective function
- Sudoku does not involve minimizing or maximizing anything
- Any arbitrary objective function works
- Define objective:
  maximize 0

Outcomes of MLP

- **Infeasible:**
  - it is impossible to fill the grid without breaking a rule
  - the pre-filled cells must break a rule and be invalid
- **Unbounded:** the objective function
  maximize 0
  is a constant function, so is certainly bounded. So our MIP will never be unbounded.
- **Solution:** To fill in the grid: for each row i and column j, search for the v such that

$$x_{ijv} = 1$$

and then write v into cell (i, j).

Big Idea: Renegotiating Problems

Sometimes we want to solve a problem, but there is an obstacle

- computational complexity: problem is *NP*-hard or undecidable
- ill-posed: don't know how to phrase problem as precise input/output statement

These are insurmountable; progress is impossible.

Big Idea: Renegotiating Problems

Sometimes we can *negotiate* on the definition of the problem

- adjust input/output def'n to correspond to an easier problem
- more specific input
- or, more general output
- ideally, still helps with the domain problem
- combines CS hard skills with domain soft skills

Approximation

Approximation: output is *nearly-optimal* but not necessarily truly optimal.

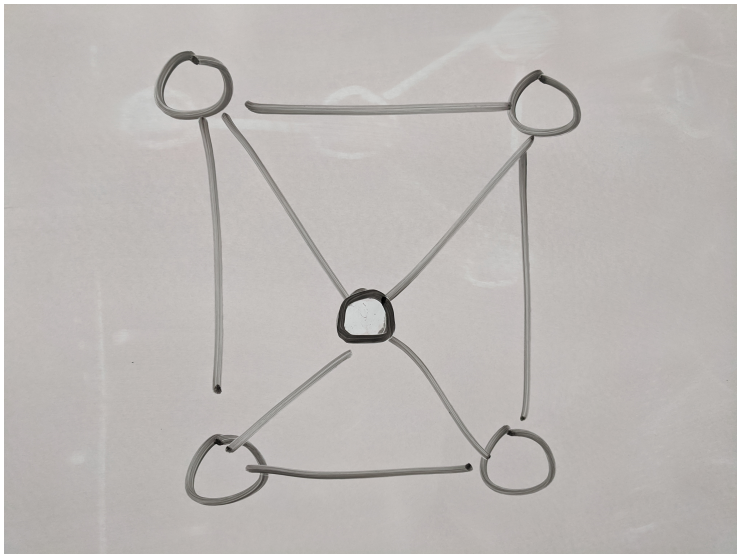
- quality is quantified, **proven**
- "approximation", "approximate" are technical terms; use other words like "decent" for informal ideas about quality
- suitable for use cases where approximate solutions are adequate
- need to rewrite problem definition
- every optimization problem has corresponding approximation problems; but these are distinct problems

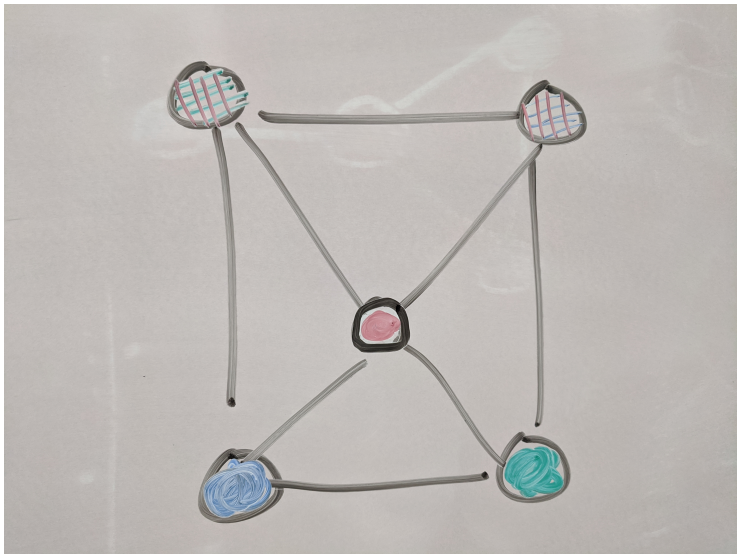
Example: optimal vs. approximate graph coloring

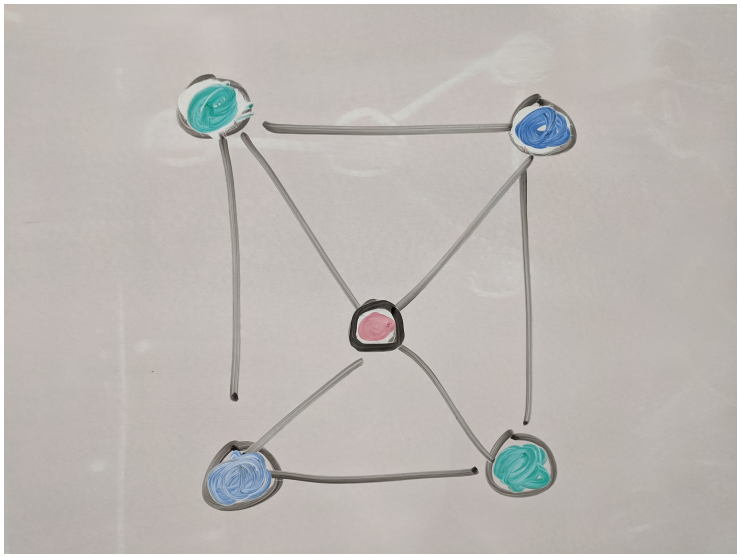
graph coloring
input: connected graph $G = (V, E)$
output: coloring c using k colors, where each vertex $v \in V$ is assigned color $c(v) \in \{1, \ldots k\}$, no pair of adjacent vertices are assigned the same color, and the number of colors k is minimal

3-approximate graph coloring
input: connected graph $G = (V, E)$
output: coloring c using k colors, where each vertex $v \in V$ is assigned color $c(v) \in \{1, \ldots k\}$, no pair of adjacent vertices are assigned the same color, **and the number of colors k satisfies $k \leq 3k^\star$, where $k^\star$ is the fewest colors possible for G**

Graph Coloring Example







Approximation vs. Other Renegotiation Approaches

Other ways of dealing with hard problems:

- say "no"
- when n is tiny, settle for exponential-time algorithm
- no *proof* of solution quality, but sometimes good enough:
  - machine learning algorithms (also, humans don't need to precisely define what counts as "correct")
  - heuristic algorithms
  - Monte Carlo algorithms

Approximation

- pros: *provable* solution quality, often fast
- con: relatively difficult alg. design and analysis

Performance Ratios

Approximation ratio $\rho(n)$: ratio between quality of algorithm's output and optimal output

- smaller ratio is better
- 1 is perfect
- ρ is defined differently for minimization, maximization problems

Performance Ratio for Minimization Problem

For **minimization** problem: if optimal quality is $C^\star$ and alg. produces quality C, by definition $C^\star \leq C$ and define

$$\rho(n) = \frac{C}{C^\star}$$

Recall 3-approx. vertex cover: # colors $\leq 3k^\star$

Performance Ratio for Maximization Problem

For **maximization** problem: if optimal quality is $C^\star$ and alg. produces quality C, by definition $C^\star \geq C$, and define

$$\rho(n) = \frac{C^\star}{C}$$

(Reciprocal of previous definition.)

Consider approximate matching.

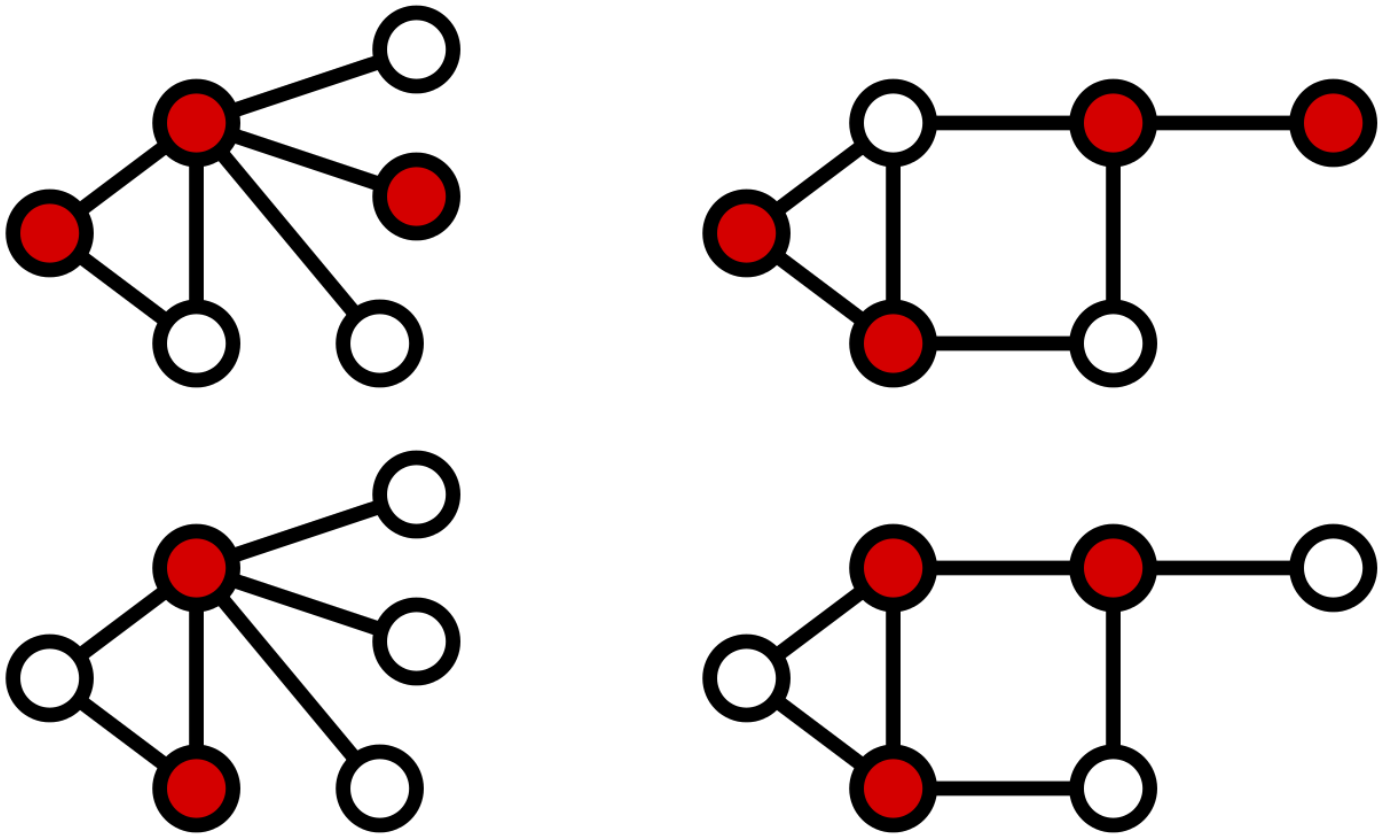
Vertex Cover Problem

vertex cover problem
input: undirected graph $G = (V, E)$
output: set of vertices $C \subseteq V$, of minimal size $|C|$, such that every edge in E is incident on at least one vertex in C

2-approximate vertex cover problem
input: undirected graph $G = (V, E)$
output: set of vertices $C \subseteq V$, such that every edge in E is incident on at least one vertex in C, and $|C| \leq 2|C^\star|$ where $C^\star$ is a minimal vertex cover for G

See Wiki page:
https://en.wikipedia.org/wiki/Vertex_cover

Vertex Cover Example



Images credit: Wikipedia user Miym, CC BY-SA 3.0,

https://commons.wikimedia.org/wiki/File:Vertex-cover.svg,

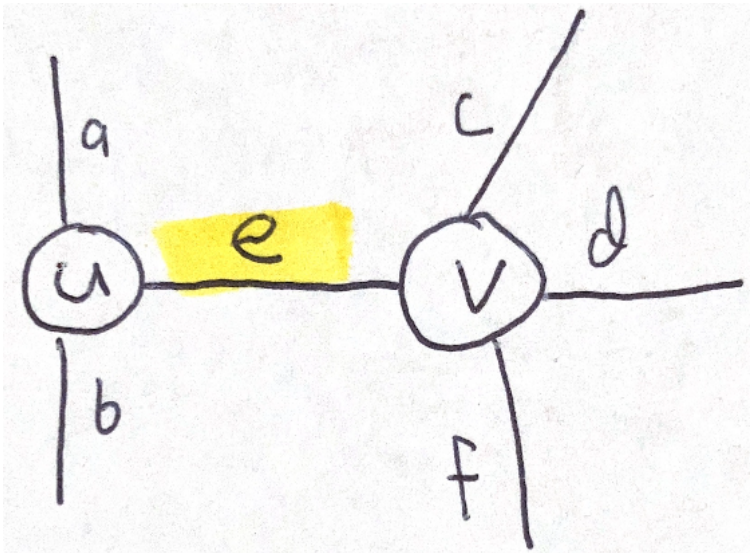
https://commons.wikimedia.org/wiki/File:Minimum-vertex-cover.svg

Vertex Cover Hardness

- vertex cover is NP-complete
- baseline algorithm:
  - exhaustive search
  - for each subset C of vertices, check whether every edge has an endpoint in C
  - return the smallest C that is a valid cover
  - $\Theta(2^n m)$ time, exponential, slow
- goal of a 2-approximate vertex cover algorithm:
  - get a decent (though imperfect) cover much faster

A Greedy Approximation Algorithm

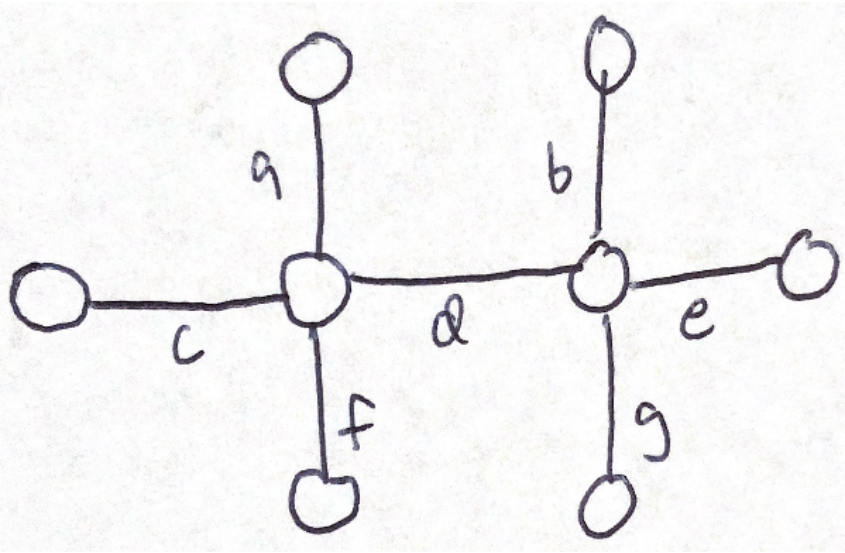
- every edge $e = (u, v)$ needs both $u \in C$ and $v \in C$
- so grab an edge $e = (u, v)$ and include u and v in C
- every other edge touching u or v is now covered, so eliminate them
- continue until every edge is either grabbed or eliminated



A Greedy Approximation Algorithm

- good: definitely finds a correct cover C
- bad: depending on the order of the "grabs", heuristic can get tricked into picking sub-optimal vertices

Example: Greedy Can Be Suboptimal



optimal edge choices: d

suboptimal edge choices: a, b (and others)

2-Approximate Vertex Cover Pseudocode

```
1: function APPROX-VERTEX-COVER(G = (V, E))
2:     C = ∅
3:     T = E                          ▷ T = edges that may be taken
4:     while T ≠ ∅ do
5:         Let e = (u, v) be an arbitrary edge in T
6:         C = C ∪ {u, v}
7:         Remove from T any edge f that is incident on u or v
8:     end while
9:     return C
10: end function
```

Efficiency Analysis: $O(m + n)$ time (assuming efficient data structures for G, T, and C)

Vertex Cover Performance Ratio

Lemma: APPROX-VERTEX-COVER is a 2-approximation algorithm.
Need: for any $G, |C| \leq 2|C^\star|$
Proof sketch:

- Let A be the set of edges chosen inside the **while** loop
- will bound $|C|$ and $|C^\star|$ both in terms of $|A|$

Vertex Cover Performance Ratio (cont'd)

- **(1)** $|C^\star|$ vs. $|A|$
- $C^\star$ is a vertex cover, so for every edge $(u, v) \in A$, we must have $u \in C^\star$ and/or $v \in C^\star$
- the "Remove from T" step guarantees that, after (u, v) is chosen, no other edge incident on u or v will be chosen and added to A
- $\Rightarrow$ each vertex $x \in C^\star$ covers *at most one* edge in A
- $\Rightarrow |C^\star| \geq |A|$

Vertex Cover Performance Ratio (cont'd)

- **(2)** $|C|$ vs. $|A|$
- the $C = C \cup \{u, v\}$ step inserts 2 vertices into C
- due to the same "Remove from T" logic, neither u nor v was already in C
- $\Rightarrow |C| = 2|A|$ (note exact equality)
- **combining (1) and (2)**

$$\begin{aligned} |C| &= 2|A| \\ &\leq 2(|C^\star|) \end{aligned}$$

- QED

Commentary on this Proof

- optimal set cover $C^\star$ is opaque
- us analysts cannot know which vertices will be in a $C^\star$
- the algorithm doesn't know what $C^\star$ is, either
- all we do know is that, due to the definition of vertex cover, and the logic of our algorithm,

  $$\#\text{ vertices in optimal cover} \geq \#\text{ iterations } \textbf{while} \text{ loop}$$

- and, due to algorithm logic,

  $$\#\text{ iterations } \textbf{while} \text{ loop} = \#\text{ vertices chosen for approx. cover}$$

- in general, to prove an approx. ratio, need
  1. to bound quality of arbitrary, opaque optimal solution; and
  2. bound quality of approx. solution the same way
